Abstract. This paper introduces $k\#\$-$rewriting systems based on earlier defined $\#$-rewriting systems but with additional pushdown memory. It demonstrates that these systems characterize an infinite hierarchy of language families resulting from the limited number of rewriting positions in every configuration during the generation of a sentence.

Key-words: $k\#\$-$rewriting systems, pushdown, $\#$-rewriting systems, infinite hierarchy, finite index, $n$-limited state grammars

1. Introduction

The most used classes of formal models in the formal language theory are grammars and automata. Grammars work as generative devices, while automata work as accepting devices. Given a grammar, it uses its rules to derive the string belonging to the language it describes from some initial string. Given an automaton, it uses its rules to decide which actions should be performed, based on its state, first symbol of its input string, and possibly on other additional information. Every string that drives the given automaton to its accepting configuration belongs to the language characterized by that automaton.

Formal language theory has introduced several language-defining models, state grammars and deep pushdown automata (see [1], [2]), based upon a combination of grammars and automata. To give a more general example, rewriting systems underlie both grammars and automata. To a more general example, rewriting systems underlie both grammars and automata. To give a more general example, rewriting systems underlie both grammars and automata, so they generalize both. Furthermore, a unified approach to the way both grammars and automata define languages were studied in [3] and [4].

In 2006, Meduna, Krivka, and Schönecker introduced a new modification of rewriting systems, called $\#$-rewriting systems (see [5]). While ordinary rewriting systems rewrite just one substring to another during one computation step, $\#$-rewriting systems rewrite in fact two substrings, where the first substring is always one symbol long and acts like state. Moreover, the success of one computation step in $\#$-rewriting systems depends
also on the number of occurrences of # in their sentential forms. If \( k \) is an upper bound limit of the number of occurrences of #, \#-rewriting systems are said to be of index \( k \). Such a restriction has an important influence to their descriptive power. While ordinary rewriting systems characterize the Chomsky hierarchy of languages, the power of \#-rewriting systems of index \( k \) coincide with the power of programmed grammars of the same index (see [5]).

In this paper, we extend \#-rewriting systems with additional storage that can contain both terminals and nonterminals and we call them \( k\#\$\)-rewriting systems. More precisely, every configuration consists of three parts: (1) the current state, (2) a string of terminals (including #), and, newly, (3) a pushdown string of terminals and nonterminals (excluding #). Below, in the string representation of such configuration, part (2) and (3) are separated by the symbol \$. From a more practical viewpoint, it is noteworthy that this string representation is applicable in theoretically oriented computational linguistics related to the fundamental study given in [6], discussing pumping lemmas for the control language hierarchy. As a matter of fact, it can be used in any practically limited scattered information processing, such as bioinformatics, including state grammar and deep pushdown automata applied to biological sequences of nucleic acids (see [7]).

After giving some preliminaries in Section 2. and introducing the formal definition with an example in Section 3., in Section 4., we show that for some positive integer, \( k \), \( k\#\$\)-rewriting systems and \( k \)-limited state grammars have the same expressive power. Finally, the concluding section outlines an open problem for further investigation.

2. Preliminaries

This paper assumes that the reader is familiar with the fundamental notions of formal language theory (see [8, 9]). For a set \( X \), \( \text{card}(X) \) denotes its cardinality and \( 2^X \) denotes its power set. By \( \mathbb{N} \), we denote a set of all positive integers. Let \( \Sigma \) be an alphabet. Then, \( \Sigma^* \) represents the free monoid generated by \( \Sigma \) under the operation of concatenation with \( \varepsilon \) as its identity element. Set \( \Sigma^+ = \Sigma^* - \{\varepsilon\} \). For \( w \in \Sigma^* \), \( |w| \) denotes the length of \( w \), \( \text{alph}(w) = \{x \mid w = uxv, x \in \Sigma, u, v \in \Sigma^*\} \) denotes the minimal subset of \( \Sigma \) such that \( w \in \text{alph}(w)^* \). For \( a \in \Sigma \), \( \text{occur}(w, a) \) denotes the number of occurrences of \( a \) in \( w \); mathematically, \( \text{occur}(w, a) = \text{card}\{u \mid w = uav, u, v \in \Sigma^*\} \). For \( W \subseteq \Sigma^* \), \( \text{occur}(w, W) = \sum_{a \in W} \text{occur}(w, a) \). For \( k \geq 0 \), if \( w \) can be expressed as \( w = xy \) such that \( k = |x| \) and \( x, y \in \Sigma^* \), then \( \text{prefix}(w, k) = x \); otherwise, \( \text{prefix}(w, k) = w \).

Let \( A \) be a set and let \( \sigma \) be a (binary) relation over \( A \). The \( k \)-fold product of \( \sigma \), where \( k \geq 0 \), the transitive closure of \( \sigma \), and the reflexive and transitive closure of \( \sigma \) are denoted as \( \sigma^k \), \( \sigma^+ \), and \( \sigma^* \), respectively. Instead of \((x, y) \in \sigma \), we write \( x \sigma y \).

By \( p : e \), we express that \( e \) has \( p \) as its label, i.e. \( p \) is a unique symbol that is associated with \( e \) and that can be used as an alternative name of \( e \). By \( p : e \in D \), we express that \( p : e \) and \( e \in D \).

A context-free grammar is a quadruple, \( G = (V, T, P, S) \), where \( V \) is a total alphabet, \( T \subseteq V \) is an alphabet of terminals, \( P \subseteq (V - T) \times V^* \) is a finite set of rules, and \( S \in (V - T) \) is the start symbol. Instead of \((A, x) \in P \), we write \( A \rightarrow x \in P \). Let \( \Rightarrow \) be a relation of direct derivation on \( V^* \) defined as follows: \( uAv \Rightarrow u xv \) if \( A \rightarrow x \in P \), where \( A \in (V - T) \) and \( u, x, v \in V^* \). By \( uAv \Rightarrow u xv [A \rightarrow x] \), we express that \( uAv \Rightarrow u xv \).
directly derives \( uvx \) according to \( A \to x \). By \( \Rightarrow_G \), we express that a relation of direct derivation, \( \Rightarrow \), is associated with a grammar \( G \). The language generated by \( G \), \( L(G) \), is defined as \( L(G) = \{ w \mid S \Rightarrow^* w, w \in T^* \} \). The family of context-free languages is denoted as \( \mathcal{L}(\text{CF}) \).

Let \( n \geq 1 \) and \( \Sigma_n = \{ a_1, b_1, a_2, b_2, \ldots, a_n, b_n \} \). The Dyck language \( \mathcal{D}_n \) over \( \Sigma_n \) is generated by the grammar

\[
(\{ S \} \cup \Sigma_n, \Sigma_n, \{ S \to SS, S \to \varepsilon, S \to a_1Sb_1, \ldots, S \to a_nSb_n \}, S).
\]

Let \( G \) be a grammar of arbitrary type, and let \( V, T, \) and \( S \) be its total alphabet, terminal alphabet, and start symbol, respectively. For a derivation \( D \): \( w_1 \Rightarrow w_2 \Rightarrow \ldots \Rightarrow w_r, S = w_1, w_r \in T^* \), according to \( G \), we set \( \text{Ind}(D, G) = \max \{ \text{occur}(w_i, V - T) \mid 1 \leq i \leq r \} \), and for \( w \in T^* \), we define \( \text{Ind}(w, G) = \min \{ \text{Ind}(D, G) \mid D \text{ is a derivation for } w \text{ in } G \} \).

The index of grammar \( G \) (see page 151 in [10]) is defined as \( \text{Ind}(G) = \sup \{ \text{Ind}(w, G) \mid w \in L(G) \} \). For a language \( L \) in the family \( \mathcal{L}(X) \) of languages generated by grammars of some type \( X \), we define \( \text{Ind}_X(L) = \inf \{ \text{Ind}(G) \mid L(G) = L, G \text{ is of type } X \} \). For a family \( \mathcal{L}(X) \), we set \( \mathcal{L}_n(X) = \{ L \mid L \in \mathcal{L}(X) \text{ and } \text{Ind}_X(L) \leq n \}, n \geq 1 \).

A state grammar (see [1]) is a sextuple \( G = (V, T, K, P, S, s) \), where \( V \) is a total alphabet, \( T \subseteq V \) is an alphabet of terminals, \( K \) is a finite set of states, \( V \cap K = \emptyset \), \( P \subseteq (V - T) \times K \times V^* \times K \) is a finite set of rules, \( S \in (V - T) \) is the start symbol, and \( s \in K \) is the start state. Instead of \( (A, p, x, q) \in P \), we write \( (A, p) \to (x, q) \in P \). Let \( \Rightarrow \) be a relation of direct derivation on \( V^* \times K \) defined as follows: \( (uAv, p) \Rightarrow (uxv, q) \) iff \( (A, p) \to (x, q) \in P \) and for every \( (B, p) \to (y, t) \in P, B \notin \text{alph}(u) \), where \( p, q, t \in K, A, B \in (V - T) \), and \( u, v, x, y \in V^* \). For some \( k \geq 1 \) satisfying \( \text{occur}(uA, V - T) \leq k \), \( \Rightarrow \) is said to be \( k \)-limited, denoted as \( \rightarrow_k \). By \( (uAv, p) \Rightarrow (uxv, q) \), \( [(A, p) \to (x, q)] \), we express that \( (uAv, p) \) directly derives \( (uxv, q) \) according to \( (A, p) \to (x, q) \). Similarly for \( \rightarrow_k \). The language generated by \( G \), \( L(G) \), is defined as \( L(G) = \{ w \mid (S, S) \Rightarrow^*_k (w, q), q \in K, w \in T^* \} \). Let \( k \geq 1 \). The language generated by \( G \) in \( k \)-limited way, \( L(G, k) \), is defined as \( L(G, k) = \{ w \mid (S, S) \rightarrow_k^* (w, q), q \in K, w \in T^* \} \). The families of languages generated by state grammars and by state grammars in \( k \)-limited way are denoted as \( \mathcal{L}(\text{ST}) \) and \( \mathcal{L}(\text{ST}, k) \), respectively.

A \#-rewriting system (see [5]) is a quadruple \( M = (Q, \Sigma, s, R) \), where \( Q \) is a finite set of states, \( \Sigma \) is an alphabet containing special symbol \# called bounder, \( Q \cap \Sigma = \emptyset \), \( s \in Q \) is the start state, and \( R \subseteq Q \times \Sigma \times \{ \# \} \times Q \times \Sigma^* \) is a finite set of rules. Instead of \( (p, n, \#, q, x) \in R \), we write \( p \#_n \rightarrow qx \). Let \( \Rightarrow \) be a relation of direct rewriting on \( Q\Sigma^* \) defined as follows: \( pu\#v \Rightarrow quxv \) iff \( p\#n \rightarrow qx \in R \) and \( \text{occur}(u, \#) = n - 1 \), where \( p, q \in Q, u, v, x \in \Sigma^* \), and \( n \in \mathbb{N} \). By \( pu\#v \Rightarrow quxv[p\#n \rightarrow qx] \), we express that \( pu\#v \) directly rewrites \( quxv \) according to \( p\#n \rightarrow qx \). The language generated by \( M \), \( L(M) \), is defined as \( L(M) = \{ w \mid s\# \Rightarrow^* qw, q \in Q, w \in (\Sigma - \{ \# \})^* \} \). Let \( k \in \mathbb{N} \). A \#-rewriting system \( M \) is said to be of index \( k \) iff \( s\# \Rightarrow^* qy \) implies \( \text{occur}(y, \#) \leq k \), where \( q \in Q \) and \( y \in \Sigma^* \). Let \( k \in \mathbb{N} \). The family of languages generated by \#-rewriting systems and by \#-rewriting systems of index \( k \) are denoted as \( \mathcal{L}(\#\text{RS}) \) and \( \mathcal{L}_k(\#\text{RS}) \), respectively.

3. Definitions

We are now ready to define \( k\#\$\)-rewriting systems.
Definition 3.1. Let $k \in \mathbb{N}$. A k\#-$rewriting system is a quintuple

$$M = (Q, V, \Sigma, s, R),$$

where $Q$ is a finite set of states, $V$ is a total alphabet, $V \cap Q = \emptyset$, $\Sigma$ is an alphabet containing $\#$ and $\$ called bounders, $\Sigma \subseteq V$, $s \in Q$ is a start state, and

$$R \subseteq (Q \times \mathbb{N} \times \{\#\} \times Q \times (\Sigma - \{\$\})*)$$

$$\cup (Q \times \{\#\} \times \{\$\} \times Q \times (\Sigma - \{\#,\$\})*)$$

$$\cup (Q \times \{\$\} \times (V - \Sigma) \times Q \times \{\#\} \times \{\$\})*$$

is a finite set of rules.

Instead of $(p, n, \#, q, x) \in R$, $(p, \#, \$y, q) \in R$, and $(p, \$, A, q, \#, \$) \in R$, we write $p_n \# \overset{\$y}{\Rightarrow} q$ instead of $(p, n, \#, \$y) \notin R$.

Let $\Xi \subseteq \bigcup_{\alpha \in \Sigma} Q(\Sigma - \{\$\})^*\{\$\}(V - \{\#, \$\})*$ be a set of all configurations of $M$ such that $\chi \in \Xi$ iff $\text{occur}(\chi, \#) \leq k$.

Let $\Rightarrow$ be a relation of direct rewriting step on $\Xi$ defined as follows:

1. $pu_\#v\$a $\Rightarrow$ quv\$a$ iff $pu_\# \Rightarrow qx \in R$, $p_u v \in R$, $v(x) = n - 1$, $p, q \in Q$, $u, v, x \in (\Sigma - \{\$\})*$, $\alpha \in (V - \{\#, \$\})*$, and $n \in \mathbb{N}$;
2. $pu\#$A\$a$ $\Rightarrow$ qu\$\$a$ iff $p u \$A \Rightarrow q u \$A \in R$, $p, q \in Q$, $u \in (\Sigma - \{\$\})*$, and $x, \alpha \in (V - \{\#, \$\})*$;
3. $p u \$A \Rightarrow pu u \$A$ iff $p u \$A \Rightarrow q u \$A \in R$, $p, q \in Q$, $u \in (\Sigma - \{\$\})*$, $A \in V - \Sigma$, and $\alpha \in (V - \{\#, \$\})*$;
4. $p u x \$a$ $\Rightarrow$ pu\$x\$a$ iff $p u x \$a \Rightarrow q u x \$a \in R$, $p, q \in Q$, $u \in (\Sigma - \{\$\})*$, $x \in (\Sigma - \{\#, \$\})*$, and $\alpha \in (V - \{\#, \$\})*$.

By $x \Rightarrow y[r]$, we express that $x$ directly rewrites $y$ according to $r$.

The language generated by $M$, $L(M)$, is defined as

$$L(M) = \{w \mid s\# \Rightarrow^* qu\$q \in Q, w \in (\Sigma - \{\#, \$\})*\}.$$

The family of languages generated by k\#-$rewriting systems is denoted as $\mathcal{L}_k(\#RS)$.

The following example demonstrates a generative capacity of k\#-$rewriting systems.

Example 3.2. Let $M = (Q, V, \Sigma, s, R)$ be a 2\#-$rewriting system, where

$$Q = \{s, p, p', p^{(1)}_1, p^{(2)}_2, p^{(1)}X, p^{(2)}Y, q, f, f(A), f(B)\}$$

$$V = \{A, B, X, a, b, c, d, 0, 1, 0_1, 1, [1], [2], \#, \$\}$$

$$\Sigma = \{a, b, c, d, 0, 1, 0, 1, [1], [2], \#, \$\}$$

and $R$ contains rules

1. $s i\# \Rightarrow p\#$
2. $p_1 \# \Rightarrow p' a\# b$
3. $p' c\# \Rightarrow p^{(1)}c\#$
4. $p_2 \# \Rightarrow p^{(2)}d\#$
5. $p^{(1)}\# \Rightarrow p^{(1)}X_1 A$
6. $p^{(2)}\# \Rightarrow p^{(2)}X_2 B$
7. $p^{(1)}X \Rightarrow p\#$
8. $p^{(2)}X \Rightarrow p^{(2)}\#$
9. $p^{(1)}Y \Rightarrow q$
10. $q i\# \Rightarrow f$
11. $f^A \Rightarrow f^A$\#$$
12. $f^B \Rightarrow f^B$\#$$
13. $f^A i\# \Rightarrow f^A 0^A$\#
14. $f^B i\# \Rightarrow f^B 0^B$\#
15. $f^A i\# \Rightarrow f^A 0^A$
16. $f^B i\# \Rightarrow f^B 0^B$
First, $M$ generates two $\#$ bounders. Second, $M$ uses rules 2 through 7 to generate the following structure

$$a^m b^m z_1 z_2 \cdots z_m \# \phi(z_m z_{m-1} \cdots z_1)$$

where $z_i \in \{c, d\}$, $1 \leq i \leq m$, $m \geq 1$ and $\phi$ is a homomorphism from $\{c, d\}^*$ to $\{A, B, [1], [2], 1, 2\}^*$ such that $\phi(c) = [1A]_1$ and $\phi(d) = [2B]_2$. Finally, $M$ uses rules 8 through 16 to finish the rewriting. Thus, the language generated by $M$ is

$$L(M) = \left\{ w \mid w = a^n b^n z_1 z_2 \cdots z_n h(z_n, i_1) h(z_{n-1}, i_2) \cdots h(z_1, i_n), \quad z_i \in \{c, d\}, 1 \leq i \leq n, i_j \geq 1, 1 \leq j \leq n, n \geq 1 \right\}$$

where $h$ is a mapping from $\{c, d\} \times \mathbb{N}$ to $\{0, 1, 0, 1, [1], [2], 1, 2\}^*$ such that $h(c, i) = [01^i]_1$ and $h(d, i) = [20^i 1]_2$.

For instance, $M$ generates $aabbdc[10011][201]_2$ in the following way

$$s\# \Rightarrow p\# \# [1]$$
$$\Rightarrow p'a\#b\# [2]$$
$$\Rightarrow p(2)a\#bd\# [4]$$
$$\Rightarrow p(X)a\#bd\#X[2B]_2 [6]$$
$$\Rightarrow pa\#bd\#[2B]_2 [7]$$
$$\Rightarrow p'aa\#bd\#[2B]_2 [2]$$
$$\Rightarrow p'(1)aa\#bbdc\#[2B]_2 [3]$$
$$\Rightarrow p(X)aa\#bbdc\#X[1A]_1[2B]_2 [5]$$
$$\Rightarrow p'(Y)aa\#bbdc\#[1A]_1[2B]_2 [8]$$
$$\Rightarrow qaabdc\#[1A]_1[2B]_2 [9]$$
$$\Rightarrow faabdc\#[1A]_1[2B]_2 [10]$$
$$\Rightarrow faabdc[1A]_1[2B]_2$$
$$\Rightarrow f(A)abdc[1A]_1[2B]_2 [11]$$
$$\Rightarrow f(A)abdc[10A]_1[2B]_2 [13]$$
$$\Rightarrow faabdc[10011][2B]_2 [15]$$
$$\Rightarrow faabdc[10011][2B]_2$$
$$\Rightarrow f(D)abdc[10011][2B]_2 [12]$$
$$\Rightarrow faabdc[10011][2B]_2$$
$$\Rightarrow faabdc[10011][2B]_2$$

4. Results

First, we prove the identity of $\mathcal{L}(ST, k)$ and $\mathcal{L}_k(\#\$RS)$ for every $k \geq 1$.

**Lemma 4.1.** Let $k \geq 1$. Then, $\mathcal{L}(ST, k) \subseteq \mathcal{L}_k(\#\$RS)$.

**Proof.** Let $G = (V, T, K, P, S, s)$ be a state grammar. Without any loss on generality, suppose that $V \cap \{\#, \$\} = \emptyset$. Now, we construct from $G$ a $k\#$-rewriting system

$$M = (Q, V', \Sigma, s', R)$$
such that $L(G, k) = L(M)$. First, we set

$$Q = \bigcup_{i=0}^{k} \{ (q; l; u) \mid q \in K, u \in (V - T)^i, 0 \leq l \leq k \}$$
$$V' = V \cup \{ \#; \}$$
$$\Sigma = T \cup \{ \#; \}$$
$$s' = (s; 0; S)$$

In $Q$, each state records three pieces of information—(1) the current state of $G$, (2) auxiliary substate of the simulation (0 is for regular state, and 1 through $k$ are for auxiliary substates), and (3) the first $k$ nonterminal symbols from the current sentential form of $G$. The positions of these $k$ symbols correspond to $\#$s in the simulation of $G$ by $M$.

Next, we construct $R$. Let

$$\text{rules}(p, u) = \left\{ r \mid r: (B, p) \rightarrow (x, q) \in P, B \in ((V - T) \cap \text{alph}(u)), p, q \in K, x \in V^+, u \in V^* \right\}$$

and let $g$ and $h$ be two homomorphisms from $V^*$ to $(\Sigma - \{ \$ \})^*$ and from $V^*$ to $(V' - \Sigma)^*$, respectively, defined as

$$g(x) = \begin{cases} 
\# & \text{for every } x \in (V - T) \\
x & \text{for every } x \in T
\end{cases}$$
$$h(x) = \begin{cases} 
x & \text{for every } x \in (V - T) \\
\epsilon & \text{for every } x \in T
\end{cases}$$

Initially, set $R = \emptyset$. For every rule $(A, p) \rightarrow (x, q) \in P$ and for every state $(p; 0; uAv) \in Q$ such that $\text{rules}(p, u) = \emptyset$ perform the following steps:

(A) If $k - |uv| \geq |h(x)|$, then add $(p; 0; uAv) \# \rightarrow (q; 0; uh(x)v)g(x)$ to $R$.

(B) If $k - |uv| < |h(x)|$, then express $v$ as $v = X_{m-1}X_{m-2} \cdots X_0$, where $X_i \in (V' - \Sigma)$, $0 \leq i \leq m - 1$, $m = |v|$, and

(i) for every $i$ such that $0 \leq i \leq m - 1$, add $(p; i; uAv)\# \rightarrow (p; i + 1; uAv)\#X_i$ to $R$;

(ii) add $(p; m; uAv)\# \rightarrow (q; 0; u)\#x$ to $R$.

Finally, for every state $(p; 0; u) \in Q$ such that $|u| \leq k - 1$ and for every $B \in (V' - \Sigma)$ add rule

$$(p; 0; u)\#B \rightarrow (p; 0; uB)\#$$

to $R$. The construction of $M$ is completed.

Due to the lack of space, we leave the formal proof that $L(G, k) = L(M)$, which is rather technical, to the kind reader. Both, $L(G, k) \subseteq L(M)$ and $L(M) \subseteq L(G, k)$ can be proved by induction on the number of derivation or rewriting steps, respectively.

\[\square\]

**Lemma 4.2.** Let $k \geq 1$. Then, $L_k(\#\$RS) \subseteq L(ST, k)$.
**Proof.** Let \( M = (Q, V, \Sigma, s, R) \) be a \( k\#\$\)-rewriting system. Without any loss on generality, suppose that \( i \notin V \) and \( \#_i \notin V \), for all \( 1 \leq i \leq k \). From \( M \), we construct a state grammar
\[
G = (V', T, K, P, \#_1, s')
\]
such that \( L(M) = L(G, k) \). First, we set
\[
V' = (V - \{\#, \$\}) \cup \{\#_i | 1 \leq i \leq k\}
T = \Sigma - \{\#, \$\}
K = \{(p; i) | p \in Q, 0 \leq i \leq k\} \cup \{(p; i; r) | p \in Q, 0 \leq i \leq k, r \in R\}
\cup \{(p; i; [r, j]) | p \in Q, r \in R, 0 \leq i \leq k, 1 \leq j \leq k\}
\cup \{(p; i; [r, X]) | p \in Q, r \in R, X \in (V - \Sigma) \cup \{\$\}, 0 \leq i \leq k\}
\cup \{q_{fail}\}
\]
\( s' = (s; 1) \)
In \( K \), each state records the current state of \( M \) and the number of \#\$\$ in the current configuration of \( M \). Sometimes, it also contains the simulated rule, \( r \), and additionally with information either about the leftmost non-\# nonterminal symbol, \( X \), or simulation progress, \( j \). Note that \( X = i \) if the simulation of a rule from \( R \) of the form \( r : p\$A \rightarrow q\$\$ \) has started. In addition, \( K \) contains a special state \( q_{fail} \) that brings \( G \) to a configuration that rules out the next derivation step in \( G \), which unsuccessfully stops the simulation of \( M \).

Let \( \tau \) be a mapping from \((\Sigma - \{\$\})^* \times \{1, 2, \ldots, k\}\) to \((T \cup \{\#_i | 1 \leq i \leq k\})^*\) defined recursively as follows
\begin{itemize}
  \item \( \tau(\varepsilon, i) = \varepsilon \), for every \( 1 \leq i \leq k \)
  \item \( \tau(ax, i) = a\tau(x, i) \), for every \( a \in (\Sigma - \{\#, \$\}) \), \( x \in (\Sigma - \{\$\})^* \), and \( 1 \leq i \leq k \)
  \item \( \tau(\#x, i) = \#_i\tau(x, i + 1) \), for every \( x \in (\Sigma - \{\$\})^* \) and \( 1 \leq i \leq k - 1 \)
\end{itemize}
We are now ready to construct \( P \). Initially, set \( P = \emptyset \). For every state \( (p; \kappa) \in K \) and for every rule \( r : p\# \rightarrow qx \in R \) such that \( n \leq \kappa \) and \( \kappa - 1 + \text{occ}(x, \#) \leq k \) perform the following steps:

(A) If \( \text{occ}(x, \#) = 0 \) and \( \kappa - n = 0 \), then add
\[
(\#_1, (p; \kappa)) \rightarrow (\#_1, (p; \kappa; r))
(\#_\kappa, (p; \kappa; r)) \rightarrow (x, (q; \kappa - 1))
\]
to \( P \).

(B) If \( \text{occ}(x, \#) = 0 \) and \( \kappa - n \geq 1 \), then
\begin{itemize}
  \item add \( (\#_1, (p; \kappa)) \rightarrow (\#_1, (p; \kappa; r)) \) to \( P \);
  \item add \( (\#_\kappa, (p; \kappa; r)) \rightarrow (x, (q; \kappa - 1; [r, 1])) \) to \( P \);
  \item for every \( 1 \leq i \leq \kappa - n - 1 \), add
    \[
    (\#_n+i, (q; \kappa - 1; [r, i])) \rightarrow (\#_n+i-1, (q; \kappa - 1; [r, i + 1]))
    \]
to \( P \);
• add \( (\#_n, (p; \kappa; [r, \kappa - n])) \) to \( P \).

(C) If \( \text{occur}(x, \#) = 1 \), then add
\[
(\#_1, (p; \kappa)) \rightarrow (\#_1, (p; \kappa; r)) \\
(\#_n, (p; \kappa; r)) \rightarrow (\tau(x, n), (q; \kappa))
\]
to \( P \).

(D) If \( \text{occur}(x, \#) \geq 2 \), then
• add \( (\#_1, (p; \kappa)) \rightarrow (\#_1, (p; \kappa; r)) \) to \( P \);
• add \( (\#_n, (p; \kappa; r)) \rightarrow (\#_n, (p; \kappa; [r, 1])) \) to \( P \);
• for every \( 0 \leq i \leq \kappa - n - 1 \), add
\[
(\#_{\kappa-i}, (p; \kappa; [r, i + 1])) \rightarrow (\#_{\kappa+n-i}, (p; \kappa; [r, i + 1]))
\]
to \( P \), where \( \eta = \text{occur}(x, \#) - 1 \);
• add \( (\#_n, (p; \kappa; [r, \kappa-n+1])) \rightarrow (\tau(x, n), (q; \kappa+\eta)) \) to \( P \), where \( \eta = \text{occur}(x, \#) - 1 \).

Next, for every state \( \langle p; \kappa \rangle \in K \) such that \( \kappa \geq 1 \) and for every rule \( r: p\#S \rightarrow q\#x \in R \), add
\[
(\#_1, (p; \kappa)) \rightarrow (\#_1, (p; \kappa; r)) \\
(\#_n, (p; \kappa; r)) \rightarrow (x, (q; \kappa - 1))
\]
to \( P \).

Finally, for every state \( \langle p; \kappa \rangle \in K \) such that \( \kappa \leq k - 1 \) and for every rule \( r: p\$A \rightarrow q\#S \in R \), add
• \( (A, (p; \kappa)) \rightarrow (A, (p; \kappa; r)) \) if \( \kappa = 0 \)
• \( (\#_1, (p; \kappa)) \rightarrow (\#_1, (p; \kappa; r)) \) if \( \kappa \geq 1 \)
• \( (A, (p; \kappa; r)) \rightarrow (A, (p; \kappa; [r, \underline{\iota}]))) \)
• \( (X, (p; \kappa; [r, \underline{\iota}])) \rightarrow (X, (p; \kappa; [r, X])), \) for all \( X \in (V - \Sigma) \)
• \( (Y, (p; \kappa; [r, Y])) \rightarrow (Y, g_{\text{false}}), \) for all \( Y \in (V - \Sigma), \) where \( Y \neq A \)
• \( (A, (p; \kappa; [r, A])) \rightarrow (\#_{\kappa+1}, (q; \kappa + 1)) \)
to \( P \). Now, the construction of \( G \) is completed.

As in the proof of Lemma 4.1, the formal proof of Lemma 4.2 has a similar structure and its technical details are left out.

\[ \square \]

**Corollary 4.3.** Let \( k \geq 1 \). Then, \( \mathcal{L}_k(\#RS) = \mathcal{L}(ST, k) \).

**Proof.** It directly follows from Lemma 4.1 and Lemma 4.2. \[ \square \]

Next, we show that \( \mathcal{L}_k(\#RS) \) is properly included in \( \mathcal{L}_k(\#\$RS) \) for every \( k \geq 1 \).
Theorem 4.4. For every $k \geq 1$. Then, $L_k(#RS) \subseteq L_k(#\$RS)$.

Proof. The inclusion $L_k(#RS) \subseteq L_k(#\$RS)$ follows directly from the definitions of #-rewriting system of index $k$ and $k#$-$\$-rewriting system. It remains to find a language from $L_k(#\$RS)$ that is not contained in $L_k(#RS)$.

For $k = 1$, such a language is $\emptyset$. As $L_1(#\$RS) = L(CF)$ (by [1] and Corollary 4.3), $\emptyset \in L_1(#\$RS)$, but $\emptyset \notin L_1(#RS)$ (see page 169 in [10]).

For $k \geq 2$, let $\Sigma_k = \{a_1, a_2, \ldots, a_{4k-2}\}$ be an alphabet. Define a language $L_k$ over $\Sigma_k$ as

$$L_k = \{a_1^i a_2^i \ldots a_{4k-2}^i \mid i \geq 1\}.$$ 

By Theorem 4 in [1], $L_k \in \mathcal{L}(ST, k)$ and since $L_k(#\$RS) = \mathcal{L}(ST, k)$, $L_k \in L_k(#\$RS)$ as well.

It is easy to see that matrix grammars of finite index $k$ generates the same language family as $L_k(#\$RS)$ (see [5] and Theorem 3.1.2 on page 155 in [10]). By an application of pumping lemma for matrix grammars of finite index (see Lemma 3.1.6 on page 159 in [10]), we can prove that $L_k \notin L_k(#RS)$. Assume that $L_k \notin L_k(#RS)$. Therefore, there exists $z \in L_k$ such that

$$z = u_1 v_1 w_1 x_1 u_2 v_2 w_2 x_2 \ldots u_l v_l w_l x_l u_{l+1}$$

with $l \leq k$, $|v_1 x_1 v_2 x_2 \ldots v_l x_l| > 0$, and

$$u_1 v_1^i w_1 x_1^i u_2 v_2^i w_2 x_1^i \ldots u_l v_l^i w_l x_l^i u_{l+1} \in L_k$$

for every $i \geq 1$. Now, consider the following cases:

- There exists $y \in \{v_1, x_1, v_2, x_2, \ldots, v_l, x_l\}$ such that $\text{card(alph}(y)) \geq 2$. In this case, there exists $i \geq 1$ such that

  $$u_1 v_1^i w_1 x_1^i u_2 v_2^i w_2 x_1^i \ldots u_l v_l^i w_l x_l^i u_{l+1} \notin L_k.$$

- All $v_1, x_1, v_2, x_2, \ldots, v_l, x_l$ are strings over one-letter alphabet. As for $k \geq 2$ it is always true that $4k - 2 > 2k$, there will be always symbols from alph($z$) that are not contained in alph($v_1 x_1 v_2 x_2 \ldots v_l x_l$). Hence there must exist $i \geq 1$ such that

  $$u_1 v_1^i w_1 x_1^i u_2 v_2^i w_2 x_1^i \ldots u_l v_l^i w_l x_l^i u_{l+1} \notin L_k.$$

Such $z \in L_k$ does not exist and therefore $L_k \notin L_k(#RS)$ for every $k \geq 2$.

The relationship between infinite hierarchies of #-rewriting systems of finite index and $k#$-$\$-rewriting systems is summed in Figure 1.

5. Conclusion

In the future, we plan to investigate these three open problem areas.

(1) Since we have a new characterization of $\mathcal{L}(ST, k)$, for some $k \geq 1$, we will study the relationship between $k#$-$\$-rewriting systems and generalized #-rewriting systems (studied in Sections 4.1.4 and 5.1.3 of [11]).
Considering [12], we intend to discuss the subject of this paper in terms of picture languages or 2D languages.

Finally, we want to relate this paper to the study given in [13], in which multi-head finite automata are capable of simulating the tape portion behind $ in \#-rewriting systems.

\[
\begin{align*}
L_1(\#\$RS) & \subset L_2(\#\$RS) \subset \cdots \subset L_k(\#\$RS) \\
\bigcup & \bigcup \\
L_1(#RS) & \subset L_2(#RS) \subset \cdots \subset L_k(#RS)
\end{align*}
\]

Fig. 1. The relations between #-rewriting systems with finite index and #$-rewriting systems.
